

ABSTRACT OF THE DISCLOSURE

A complex-type image forming device operative for a first function (copy function) and a second function (printer function or facsimile function) is reduced in waiting time for a user to use it for the copy function. More specifically, the image forming device comprises: an image forming main body operative in at least two different functions including a first function and a second function, a first output (copy output) having an image formed by said first function and a second output having an image formed by said second function being discharged from a same paper outlet; and a finisher including a first bin for receiving the first output (copy output) and a printer bin for receiving the second output, which are selectively set in the position at the paper outlet such that, when the second bin is in the position at the paper outlet, if an original to be copied is set, or if an automatic original feeder or a platen is raised, the second bin is replaced by the first bin.
